Abstract

PostScript definitions collected in my `PSlib.eps` library and documented as e-book catalogue is presented. Now and then variant pictures have been included from `pic.dat` which comes with `Blue.tex`. Old Metafont codes have been included which may be useful for Metapost programmers. Variants of pictures enriched by postprocessing in Photoshop show other possibilities. Escher's doughnut is a teaser which has to be done in Metapost. Next to `PSlib.eps` comes the file `PDFsfromPSlib`, which contains the pictures in `.pdf` format. The complete `PSlib.eps`, `PDFsfromPSlib` as well as the catalogue as e-book, will be released, on `www.ntg.nl`, on occasion of NTG's 25th lustrum which will be celebrated in the fall of 2014. A prerelease has been offered to the GUST's file server. The (static) library for TEX alone pictures, `pic.dat`, packaged with `Blue.tex` in the 90-ies, will be redistributed as well. The Lorenz, Rössler and Hénon attractor pictures have been included. Comments, suggestions and improvements as well as contributions are welcomed: kisa1@xs4all.nl.

Introduction

Gutenberg organized in Toulouse in the 90-ies a meeting themed Graphics and TEX. Later, especially after Metapost had been released in the public domain, GUST paid attention to graphics. Piotr&Piotr developped `PSView`. LaTEX came with its picture environment and Knuth c.s. developed the `gkp`-macros with the picture environment functionality for use in plain TEX. `Blue.tex` appeared with its library `pic.dat` of TEX alone pictures, biased by the `gkp`-macros. On the EuroTEX92 in Prague Karel Horak showed his math pictures created by Metafont.[1] Later Timothy van Zandt released `PSTricks`, which uses PostScript as the graphics engine and LaTEX's picture environment as user interface. Herbert Voß maintains and extends `PSTricks`. PostScript was there all the time, since 1985 to be precise, but ... was apparently overlooked for graphics, except by Don Lancaster, who came with his `PSSecrets` and `Gonzo` collection.[2] PostScript was in use as (abstract) page description language for the upcoming laser printers.

In relation to TEX, we could in the mid-90-ies include `.eps` pictures in documents via the `\psfig` command, to be processed by `DVIPS`.[3] Jackowski developed `MFtoEPS`, to transform Metafont pictures into

[1] Karel works nowadays in Metapost, with `.eps` and `SVG` output.

[2] Gonzo utilities facilitate using PostScript as formatter for texts. Don does not use local dictionaries for library robustness.

[3] My papers of that time can't be processed by pdfTEX. -;(. They have to be adapted and the pictures must be converted into `.pdf`, `.jpg`, ...

PostScript for inclusion in TEX documents. Alas, pdfTEX does not allow direct inclusion of `.eps` files, a retrograde. Happily, ConTEXt not only allows inclusion of `.eps` files, but also works interactively with Metapost.[4]

Of my ≈25 years of involvement with, and using, TEX, I spent ≈5 years on developing `Blue.tex` and ≈20 years on creating and collecting pictures. Lauwerier's BASIC pictures, especially his fractals, I have been translated into PostScript. As an aside I exercised HTML for my WWW-site.
`PSlib.eps` was introduced at the EuroTEX2009. The library facilitates programming in PostScript. Hundreds of codes for the pictures are stored in a ordered way, facilitating its use. The catalogue is the accompanying documentation,[5] where next to the code the result of the code has been shown. It contains Adobe's Blue book `def`s as starting point. Much more, what I needed, has been added. The collection has been tested by example. I don't claim that it has been thoroughly tested nor is the collection robust, although the numerical concept robustness does not apply to graphics, in general, it occurs. Since EuroTEX2012 it has grown substantially. Older PostScript codes with local dictionaries have been added. For the 25^{th} lustrum meeting of NTG, in the fall of 2014, I decided to make the library more easily available, and come up with a catalogue, such that the desired code for the wanted graphics can be more easily spotted and used, hopefully. Numerici have their program libraries, we should have our catalogues for pictures, to start with Adobe's Blue book collection and my `PSlib.eps` extensions. I consider catalogues for graphics useful, because we lack a taxonomy, the world of pictures is too diverse. May the catalogue contribute to the 'literature' of PostScript graphics programming. May PostScript start a second glorious graphics life. Hang on and enjoy!

Why PSlib.eps?

The idea of a library of pictures I already realized in `Blue.tex` in the 90-ies. The collection is called `pic.dat` and will also be redistributed along with `PSlib.eps`. It contains graphics by TEX alone via the macros of Graham-Knuth-Pasternak, the gkp-macros.

PostScript is a powerful language for graphics. But ... it is not enough. Extended with `def`s as given in Adobe's Blue book makes the use of PostScript feasible. Reality has it that Adobe's Bluebook is apparently not enough for programming in PostScript. Why?

My answer is

- there are not enough Blue book `def`s, there are hardly no contributions from the community
- the viewer and convertor Acrobat Pro is not in the public domain; `GhostView` and `PSView` appeared later
- the `def`s have not been made easily available, there was no PD PostScript library file on the WWW
- MetaPost is of higher level, with its inheritance of the beautiful Metafont language, which is more in use than PostScript, within the TEX community, Knuth included
- Adobe has abandoned Type 1 fonts in favour for OTF, and seems no longer to support the `run` command, which I use for library inclusion[6]
- and, indeed ... PostScript is unusual, low-level, difficult and error-prone to program in, alas. But ... if you do, the rewards are more than enough. We should finish up our programming of pictures by collecting the pictures and their codes into a library and document it, in for example the accompanying catalogue.

MetaPost has an explicit datastructure for paths which comes with nice operators such as `cutbefore`, `cutafter`, `intersectionpoint`, `interpath`, and `intersectiontimes`, which I used in the Metapost code for Escher's doughnut in order to cope elegantly with the hidden lines. PostScript has the `arc` operator, for circular arcs. PostScript has no explicit paths. Nor has it a picture datastructure. PostScript has the powerful `flattenpath` which delivers an arbitrary path as a broken line, of which the points can be used by `pathforall`. By these tools the length of a path can be (approximately) calculated by Blue book's `pathlength`, for example. The absence of the path and picture datastructures in PostScript is a big lack. We will concentrate on graphical shapes and leave the glorious laserwriter history for what it is. Having said that, let us move on and see what kind of graphics can be written in PostScript.

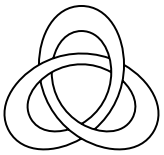
However, ... 20 years after the birth of Metapost, I still don't have a

[4] An example where TEX-Graphics interaction occurs naturally is in typesetting crosswords. But, ... a crossword is a simple graphic, so we can do with TEX alone.

[5] Physical thick, logical thin!

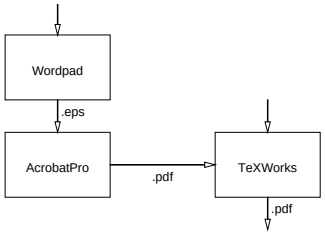
[6] Your old Acrobat Pro 7 is a treasure for converting `.eps` into `.pdf` and viewing it. Cherish Acrobat Pro 7!

pleasing Metapost working environment on my PC.[7] The TEXlive DVD does not provide me such an IDE, except as integrated part of ConTEXt. Besides, much graphics can be programmed in PostScript, as is demonstrated in my `PSlib.eps`. A notational exception is the Escher doughnut, and ilks, with its hidden lines.



In my `PSlib.eps` catalogue the Blue book `def`s have been made digitally available and extended by local dictionaries. This collection has been extended by `def`s of my own and some collected from the WWW.[8] A couple of hundreds of `def`s emerged over the past 20 years. It has been strived after that `def`s can be read, understood, reused and adapted to your circumstances. Simplicity of use is paramount. The accompanying `PDF`s have also been collected and can be reused as such. Some graphics programs are no longer relevant, for example Adobe's program for a pie chart, because of special and easy to use packages, not in the least the wealth of LaTEX packages.

```
%!PS-Adobe-3.0  EPSF-3.0
%%Title: Flowchart TeX processing and PS inclusion
%%BoundingBox: -101 -31 102 221
%%BeginSetup
%%EndSetup
%%BeginProlog
(c:\\PSlib\\PSlib.eps) run
%%EndProlog
flowchartTeXandPS   showpage
%%EOF
```



The first 6 lines are standard overhead for the kind of file, `!PS` means PostScript, providing values for the `BoundingBox`, specifying the library and its loading via `run`, cropping of the graphics to the `BoundingBox`, via the `BeginSetup` and `EndSetup` duo, `BeginProlog` and `EndProlog` enclose the needed `def`s (for example the library) and finally the invoke of the `def`: `flowchartTeXandPS`.

For the invoke one just has to known the name of the library `def` and its parameters. The parameters are documented in the code. The code is as extra supplied in the library contributions in this catalogue. Adding the library definitions to the example of use makes the example look more complex, but ... has been done on purpose to facilitate adaptability, sacrificing simple look-and-feel. However, this approach supports stand-alone use.

Processing the graphics separately and include the resulting `.pdf`, or converted `.jpg` which is more efficient in TEXworks, into your AnyTEX(, or Word, or ...) document, adheres the Separation of Concerns principle. A wider audience than the TEXcommunity, such as PostScript users, users of Word, ..., is served. `PSTricks` based packages look nice and easy, but they suffer intrinsically from the deficiency of LaTEX's picture environment, as 'graphical language,' such as the limited orientation of lines. But, ... the advantage is that the user is hidden from PostScript, does not have to know PostScript.

Why PostScript?

The use of a programming language has two aspects: the richness and power of the language proper and the ease of working in an IDE.

PostScript language The language was designed by Adobe, and introduced in 1985, as a device-independent page description language with powerful graphics capabilities, with initially $\approx$ 400 operators — i.e. built-in procedures of the system dictionary — in PostScript level 1, with substantial more in PostScript level 3. The extensive graphics capabilities are embedded in the framework of a general-purpose programming language. The language includes a conventional set of data types, such as numbers, booleans, arrays and strings; control primitives, such as conditionals, loops and procedures; and some unusual features, such as dictionaries, font transformation matrix, next to higher-level structures, such as patterns and forms. These features enable application programmers to define higher-level operations that closely match the needs of the application and

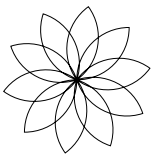
[7] Troy Henderson has his Metapost viewer, which can be accessed and used remotely. It is just a pity that he has not released a local, strand-alone version.

[8] Operators given in Lancaster's PSSecrets are hard to read and yielded non-working results. For example his Archimedian spiral, where he did not use polar coordinates, is unnecessarily complicated and did not work. On the other hand his Fonts for Free are a gem.

then to generate commands that invoke those higher-level operations. The LRM 3 is the defining document for the syntax and semantics of the language, the imaging model, and the effects of the graphics operators.

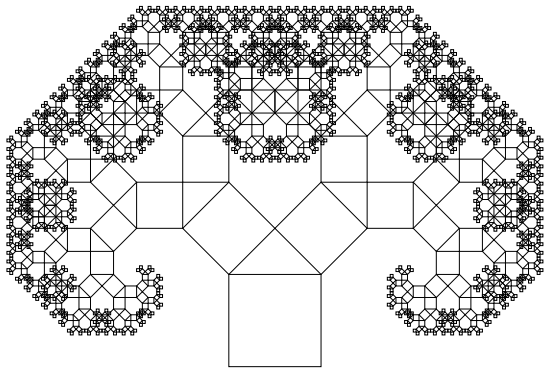
Powerful concepts

- A user space which can be altered: 'the coordinate system's origin may be *translated*, moved to any point in user space; the axes may be *rotated* to any orientation; the axes may be *scaled* to any degree desired; the scaling may be different in the x and y directions.' Reflection and skewing are also supported. My favourite illustrations of the US concept are a stylistic flower and the recursive programming of the Pythagorean tree, which is all about drawing a square in repeatedly transformed US.



← Stylistic Flower

```
%!PS-Adobe-3.0 EPSF-3.0
%%BoundingBox: -26 -26 26 26
%%BeginSetup
%%EndSetup
/r 18 def
10 {0 r r 270 360 arc
      r 0 r   90 180 arc
     36 rotate} bind repeat
stroke showpage
```



Pythagorean Tree →
BachoTEX 2011 pearl

Another nice example of the usefulness of transforming US is to create a path of an ellipse by the use of the `arc` operator, for example `1 2 scale 0 0 25 0 360 arc` (Courtesy the Blue Book, but ... be aware of the fact that the pen width has been scaled too).
To translate the centre of the coordinate system, default in the left lower corner of the current page, was the first thing I used to do. No longer necessary for my stand-alone illustrations in an EPSF program, which begin with the 4 lines as given in the stylistic flower example.

- The colour spaces, which notion was introduced in PostScript 2 of 1991, and elaborated upon in 1997 in PostScript 3, with among others much more efficient shading functionality. In PostScript 1 there were already the concepts colour mode and half-tones, with operators `setrgbcolor` and `setgray`, which were generalized in level 2 into `setcolorspace` with `setcolor`. The chapter headings of the level 1 Red and Blue Books reflect the gradients, or smooth shading, functionality.

Inspired by The Green Book p139
Much can be learned from this example
which was state of the art in 1985
Level 3 features rich colour shading

```

The number of pages of the PostScript level 3 LRM has increased to 912p, while the number of pages of the level 1 LRM is 321p. See Appendix A of the LRM 3 for the ways the PostScript language has been extended with new operators and other features over time. The language versions are upward compatible.

- Handy and useful optimizations, such as `rectstroke rectfill userpath selectfont` ...
  but ... don't use `store` in library procedures instead of `def`, with variables which **are intended** to have a local scope. Use a dictionary local to the library procedure for variables.
- The graphics state, with commonly used operators `gsave grestore` ... .
- The current page, the abstract page, the raison d'être concept behind PostScript, to be rendered by the interpreter in the rendering device (printer, screen, ...), commanded by the `showpage` operator.
- Variability of fonts by the font transformation matrix as argument of `makefont`, with scalability, mirrored fonts (as in XeTeX) smallcaps, and outlines as obvious examples.
- Stacks `operand dictionary graphics state execution`
- Immediately evaluated names, i.e. `//name` is immediately replaced by its value; useful for named constants.
- `bind` operator which looks up values of the **operator** names in the procedure operand and replaces these by their values, the so-called early binding, and returns the modified procedure. It enhances efficiency and robustness against (unintended) change of used operators, especially in library procedures. Optimize loop bodies too by `bind`.
- Idiom recognition feature of Level 3. A functionality added to the bind operator, which can be switched on/off by setting the user parameter `IdiomRecognition`. Bind can find and replace commonly occurring operators, called *idioms* by operators of higher quality and/or better performance. For example PostScript level 2 shading operators are replaced by PostScript level 3 improvements, silently behind the scenes, with new snazzy codes.
- `execform` for repeatedly placing a graphic, e.g. a logo, a fill-in form, ... efficiently (since level 2).

Operator groups, with a few operators named from each group:

- operand stack `pop exch dup ...`
- arithmetic and math `add div ... srand`
- array `array ... getinterval`
- dictionary `dict ...dictstack`
- string `string ... run ... token`
- relation, boolean, and bitwise `eq ... bitshift`
- type, attribute, and conversion `type ... cvs`
- file `file = == ... echo`
- file inclusion `run`
- virtual memory `save restore ...`
- miscellaneous `bind null usertime version`
- graphics state `gsave grestore ... currenttransfer`
- coordinate system and matrix `matrix ... invertmatrix`
- path constructing `newpath`, `moveto lineto curveto arcto ... clip eoclip ... charpath ...`

  Only one path is possible, although by juggling with several graphics states one may maintain several collateral paths
- painting to the current page of
  paths `stroke` paints lines, `fill eofill ...` fills an area
  strings `show ...`
  a sampled image `image shshow ...`
- device setup and output `showpage ...`
- character and fonts `findfont scalefont setfont` (or level 2 onward optimized concatenation of the 3 into `selectfont`) `makefont` (transforms more general than `scalefont`) `... kshow ... cshow ...`
- font cache `setcharwidth ...`
- errors `dictfull ...VMerror`.

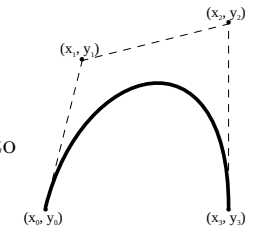
Overwhelming, isn't it?

Let us pick out a few, which I use most of the time, apart from the arithmetic, math and relation operators, whose use we are already familiar with from our favourite programming language.

`def` associates names with procedures or values available on the operand stack, and stores the associated pair in the current dictionary

`run` includes the file given in parenthesis
`moveto` creates the starting point of an (internal) path
`stroke` and ilks, to paint the path to the current page
`lineto` adds a line to the current path
`curveto` adds a curve to the current path
`arc, arcn` adds a circular arc to the current path
`image` to render the (bitmap) image onto the current page
`gsave` pushes the current graphics state on the gs-stack and creates a new current one
`grestore` pops the (top) graphics state off the gs-stack and makes it the current graphics state, en passant obseleting the graphics state in use
`makefont` is used by Don Lancaster (and undoubtedly by others) for creating a variety of fonts from the available ones. He calls his collection 'Fonts for Free'. I love his embossed variant
`kshow` I used kerning show in my BachoTEX 2010 pearl for the typesetting of π-decimals along a spiral
`forall` handy for creating concise code, used for example in my BachoTEX 2010 pearl.

curveto



The language (version 3) is stable and flexible, also called extensible, meaning one can add procedures. It is the industry page description standard language. Programs are interpreted, line by line, not compiled, which at the time was important because of small memories. It is maintained by Adobe — the stewards of PostScript — and already with us for more than 25 years! Interpreters are generally provided by 3^{rd} parties, especially the interpreters which come with printers.

For graphics `lineto`, `curveto` and `arc,` and ilks, is what makes the drawing. Let us assume a_0 is the current point.

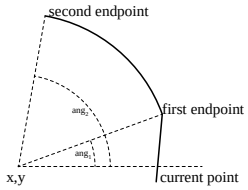
a_1 `lineto` adds a straight line to the path.

A point $z(t)$, t∈[0,1] on the line is given by $z(t) = (1-t)a_0 + ta_1$.

a_1 a_2 a_3 `curveto` adds a B-cubic to the path with end point a_3 and control points a_1 and a_2.

A point $z(t)$, t∈[0,1] on the B-cubic is given by $z(t) = \sum_{k=0}^{3}(1-t)^{3-k}t^k a_k$.

x y r ang_1 ang_2 `arc` appends a counterclockwise arc of a circle to the current path, possibly preceded by a straight line segment. The arc has (x,y) as center, r as radius, ang_1 the angle of a vector from (x,y) of length r to the first endpoint of the arc, and ang_2 the angle of a vector from (x,y) of length r to the second endpoint of the arc.



Knuth, in the Metafont book, paid much attention to a path through a set of points. A smooth curve through a set of points is not available in PostScript, as such.

The Red, Green and Blue books — Reference Manual, PostScript Language Program Design, respectively Tutorial and Cookbook — are published by Addison-Wesley and also available for free on the WWW, even the level 1 and 2 (774p) LRM's. The Blue Book, which was aimed at to set a standard for effective PostScript programming, contains examples of procedures, such as `oshow outsidecircletext insidecircletext pathtext pathlength printposter DrawPieChart centerdash smallcaps` and `arrow`, to name but a few.[9] The Red Book is indispensable. The Green Book is about software engineering in PostScript, not only to get the programs to work, but to create correct, readable, efficient, maintainable and robust PostScript programs. The underlying goal is to develop a printer driver. There is also an Adobe White Book about Type 1 fonts, also for free on the WWW. Mnemonics: the RGB-collection of Adobe :-). PostScript programs, in ASCII, are generally generated by programs, hardly self-written. They facilitate exchange of (stand alone EPSF) picture descriptions, and of course (the pages of) a complete publication. The structuring conventions of Appendix C of the Red book level 1 have grown out into an Adobe Technical note #5001, 109p. Nowadays, illustrations are easily exchanged in `.pdf`, and everybody can view them everywhere, because of the ubiquitous, free Acrobat reader. The Mathematica reader is also freely available, and facilitates the exchange of Mathematica `notebooks`. The exchange of ASCII PostScript goes without problems and is useful.

Although a powerful graphical language, PostScript is considered low-levelish by the TEX community at large. They favour John Hobby's preprocessor MetaPost, Knuth included, with exceptions: Taco Hoekwater,

[9] The procedure texts and the examples are available on the WWW as a UNIX shell archive. I have assembled the procedures into a `BlueBook.eps` library, which is system independent and also incorporated in `PSlib.eps`.

me ... . Taco includes PostScript on-the-fly in `escrito`, his PostScript compatible interpreter in Lua. He is also on the Metapost maintenance team and works on extensions of Metapost. At BachoTEX 2010 he announced the release of Metapost2.000.

'PostScript is underestimated and underused,' to quote Taco Hoekwater.

'I agree with him ... I'm not saying he is right ;-),' well ... he is.

IMHO, a little bit of PostScript does not harm. On the contrary, you will benefit from the general-purpose programming language framework, the imaging model, or you may extend your knowledge about the interactive system for controlling raster output devices, but ... self-study is dangerous. What we need is a teacher à la John Deubert who thoroughly understand the PostScript concepts. John in his Acumen Journal pays attention to among others the relation of PostScript to `PDF` and `XPS`, and gives many nice, good and useful examples, clearly explained line by line.

From the LRM: 'PDF lacks the general-purpose programming language framework of the PostScript language. A PDF document is a static data structure that is designed for efficient random access and includes navigational information suitable for interactive viewing.'

Finally, and in contrast with TEX, a mnemonic

All what you type in PostScript are

comments after %

numbers

operators

names to be looked up in the dictionaries, and at last

strings which contain text.

From the LRM

'The interpreter manipulates entities called PostScript objects. Some objects are data, such as numbers, boolean values, strings, and arrays. Other objects are elements of programs to be executed, such as names, operators, and procedures.'

In TEX the source is the text of the publication, interspersed with as few markup commands as possible, at least that is what Knuth aims at in his minimal markup style, which I love and practice too.

So ...

`add def ...` are names to be looked up in the dictionaries

`( < / [ ...` are operators:

- `(` starts a string, where all is interpreted as text, with `\` as escape character; a TEXies niche
- `<` starts a hexadecimal string, consisting of the 'digits' in the hexadecimal system `0,1, ... 9, a, b, c, d, e, f`, commonly used in the executable array, ie, procedure, as argument for the `image` operator
- `/` starts a literal name
- `[` starts an array, which may contain heterogeneous elements, in contrast with other languages.

Be aware of the difference between `name` and `/name`. The first is a `name` to be looked up in the dictionaries, while the slash in the second starts a *literal* name, which is only pushed on the operand stack, without execution. Unlike other programming languages such as PASCAL there are no reserved words.

Comments start with % Comments are used for structuring. Special comments are

- `%!` the start of a PostScript program with `%!PS-Adobe-3.0 EPSF-3.0` the complete line for illustrations to be encapsulated
- `%%` at the beginning of a line starts structural information about the PostScript program, as explained in Appendix C of the LRM version 1, or see ATN #5002; syntax `%%<keyword>: parameter values`.

EPSF Encapsulated PostScript File format Looking more closely at the `.eps`, which resulted from `.mp`, I found that header comments of a PostScript program starting with the error-prone mumbo jumbo

```
%!PS-Adobe-3.0 EPSF-3.0
%%BoundingBox:  llx lly urx ury
%%BeginSetup
%%Endsetup
```

yields the image cropped to the supplied `BoundingBox: llx lly urx ury`, centred on the page, when processed by Acrobat Pro 7.1.[10] Explicit translation of the origin via `... translate` is no longer necessary in an EPSF with a BB around the origin. Very Handy! Not only very handy ... also with better results than my old way via selecting, copying and the reuse of the copy from the clipboard. The dimensions of the BoundingBox can be requested for in the program, to create a perfect cropped illustration.

From Adobe Technical Note #5001 PostScript Language Documents Structuring Convention Specification, the following about the keyword `EPSF-3.0`

... `EPSF-3.0` states that the file is an Encapsulated PostScript Format, which is primarily a PostScript language file that produces an illustration. The EPS format is designed to facilitate including these illustrations in other documents. ...

Appendix H of the LRM version 2 details on EPSF, which by the way is not included in the LRM 3.

Contents of the library

`PSlib.eps` contains constants, `def`s for operations, `def`s for pictures, and dictionaries which are coupled to the `def`s.

Constants are for example

- `/sqrt2 1.414213562 def`
  `/sqrt3 1.732050808 def`
  `/sqrt5 2.236067977 def`
  `/pi 3.14159265358979 def`
  `/reus 2 30 exp dup 1 sub add def` ie 2.14748e+09.
- font abbreviations, such as `/H14pt /Helvetica 14 selectfont def`
- colour presettings, such as `/lightred{1 0.3 0 setrgbcolor}`.

Definitions for operations, the utilities

Definitions for 2D pictures For example the flowcharts, Escher, Soto, Schrofer, ...

Definitions for 2D fractal pictures mostly on the square inch as examples of 20th century Math geometry

Definitions for 2D pictures as projection of 3D emulated objects For example a sphere, pictures of the emulations of Gabo's constructions.

```
/linearconstructionno1{linearconstructionno1dict begin

```

Structure of each listed code contribution

The approach is similar as adopted in Adobe's Blue book. Of each code included in the library, `PSlib.eps` cq `Bluebook.eps` the example of use is listed. The code is also included. The library codes used are mentioned in the code now and then. At the right of the code the resulting picture is shown. Variants are included.

Utilities

A few utilities have been selected and discussed, which exhibit PostScript programming paradigms.

Length. A too simple operator? Not so.

One must circumvent intermediate (numerical) overflow, and... use the stack only. Moreover, the name `length` is already in use as a so-called polymorphic operator — takes different kinds of arguments — also called an overloaded operator in Ada, for example.

$$\begin{aligned} |(x,y)| &= \sqrt{x^2+y^2} \\ &= |y|\sqrt{1+(x/y)^2} \qquad \text{numerically better if} \quad |y| \geq |x| \\ &= |x|\sqrt{1+(y/x)^2} \qquad \text{numerically better if} \quad |x| \geq |y| \end{aligned}$$

```
/size %x y ==> sqrt(x^2+y^2) %not robust against 0 0 on the stack

    }ifelse
}def
```

The operator is related to the polar coordinates (r, ϕ) of a point (x, y). In PostScript the angle ϕ can be obtained via the `atan` operator; for the size r one has to provide an operator, length, oneself.

Overloading length[12]

```
%!PS Overloading length. Taco Hoekwater April 2010
/PSlength {length} bind def % save old meaning
/lengthdict 5 dict def
lengthdict /arraytype   {PSlength} put
lengthdict /dicttype    {PSlength} put
lengthdict /stringtype  {PSlength} put
lengthdict /integertype {size} put
lengthdict /realtype    {size} put
/length { lengthdict begin dup type exec end} def
```

```
%Test
(whatever) length pstack pop
[1 2 3] length pstack pop
3 dict length pstack pop
3 4 length pstack pop
```

pathlength is part of Adobe's Blue book P5 p143, Centered dash patterns. The procedure `pathlength` computes the length of any given path. It does so by first flattening the path with the `flattenpath` operator. `flattenpath` converts any `curveto` and `arc` segments in a path to a series of `lineto` segments. Then the procedure `pathforall` is used to access each segment in the path, find its length and add the length to a total. A PostScript programming paradigm.

Mean of two points The problem is to calculate .5[p_1, p_2]. Too trivial?

[12] Courtesy Taco Hoekwater

I found it worthwhile to communicate, because the operator makes use of the stack only. Stack-oriented PostScript, different from the PostScript I used in my `Just a little bit of PostScript`, of old.

```
/mean%p0 p1 on stack ==> .5[p0, p1] i.e. the coordinates of the mean
 {exch  4 -1 roll add .5 mul 3  1 roll add .5 mul}def
```

More general is the calculation of a point on the line between the two points. The `mediation` operator: t[p_1, p_2], t$\in [0,1]$.

```
/mediation {% a b t ==> c. c is weighted average of a and b; c = a * (1-t) + b * t
dup 1 exch sub 4 -1 roll mul
3 1 roll mul add
} bind def
```

Rotation of a point Despite PostScript's functionality to rotate user space, I needed an operator to rotate just points. I chose conform the PostScript tradition that a positive angle rotates counterclockwise.

x y angle `rot` x' y', rotates the point x y over the angle `angle` in degrees, counter-clockwise in the PostScript tradition

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}$$

```
/rotdict 6 dict def
/rot %x y phi: point and angle of rotation (counterclockwise) ==>x y coordinates of point after rotation
{rotdict begin
 /phi exch def /y exch def /x exch def
 /xaux x phi cos mul y phi sin mul sub def
 /y     x phi sin mul  y phi cos mul add def
 /x xaux def
 x y
 end } def
```

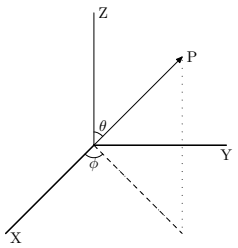
Projection of a point, operator ptp. For projections I specify the graphics in 3D and project the data onto the plane by the operator `ptp` with viewing angles as parameters.[13]

- num_1 num_2 num_3 ptp num_1 num_2, projects the 3D point on the plane with viewing angles ϕ and θ

The projection formula, with ϕ and θ viewing angles, reads

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} -\cos\phi & \sin\phi & \\ -\sin\phi\sin\theta & -\cos\phi\sin\theta & \cos\theta \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix}$$

```
/ptp{% point x y z ==> x' y'
       % use: /pair { x y z ptp } def
       % parameters: a, b viewing angles
   0 begin
   /z exch def/y exch def/x exch def
   x neg a cos mul y a sin mul add
   x neg a sin mul b sin mul y neg a cos mul b sin mul add
   z b cos mul add
   end}def
/ptp load 0 3 dict put
```



Indispensible. A practical variant with **f**ixed viewing angles, `ptpf`, is part of the `PSlib.eps` library too.

dotsandnames I consider it convenient to mark points in a picture with their names. I decided to supply the names of the points as a string in an array. Each name, a1 for example, is a definition which contains the coordinates of the point a1.

```
/dotsandnames{%[ str,..., str]==>
%str is a name, which stands for a pair, such as in pair moveto
{dup cvn load exec moveto (.) H15pt setfont centershow
                              H10pt setfont show}forall
}def
```

[13] The projection I also coded in MetaPost.

A nice use of `forall` and of using the contents of the name and the name itself. `dotandnames` is used in the emulations of Gabo's constructions. A PostScript programming paradigm.

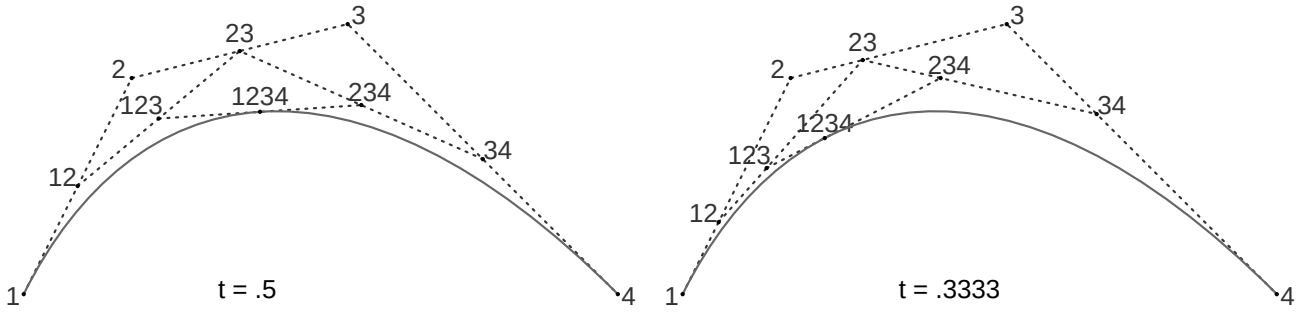
tonSpline yields the coordinates of a point on a spline given by the points (a0,a1,a2,a3)[14] as function of the time parameter $t \in [0,1]$: $z(t) = \sum_{k=0}^{3}(1-t)^{3-k}t^k a_k$. Algorithmically,[15]

$$z(t) = (1-t)\Big((1-t)\Big((1-t)a_0+t\,a_1\Big)+t\,\Big((1-t)a_1+t\,a_2\Big)\Big)+t\Big((1-t)\Big((1-t)a_1+t\,a_2\Big)+t\,\Big((1-t)a_2+t\,a_3\Big)\Big)$$

The (vector) value $z(t) = a_{0123}$, of the B-cubic characterized by a_0, a_1, a_2, a_3 for the value of the (time) variable t can algorithmically also be described as

$$\begin{matrix} a_0 \\ a_1 \\ a_2 \\ a_3 \end{matrix} \rightarrow \begin{matrix} a_{01} = a_0\,(1-t) + a_1\,t \\ a_{12} = a_1\,(1-t) + a_2\,t \\ a_{23} = a_2\,(1-t) + a_3\,t \end{matrix} \rightarrow \begin{matrix} a_{012} = a_{01}\,(1-t) + a_{12}\,t \\ a_{123} = a_{12}\,(1-t) + a_{23}\,t \end{matrix} \rightarrow a_{0123} = a_{012}\,(1-t) + a_{123}\,t$$

Graphically, Knuth displayed in the Metafont book p13 the determination of a point on a cubic spline.



The PostScript operator in `PSlib.eps` has been written by Piotr Strzelczyk.

Intersection of 2 straight lines. This functionality was needed when I imitated GUST's batteship logo in PostScript. Under the hood 2 linear equations in 2 unknowns have to be solved. The operator is called `intersect`.

```
/intersect {%p1 p2 p3 p4 -> x y
makecoef 7 3 roll  makecoef  solveit}def
```

The library contains also an operator for solving 3 linear equations in 3 unknowns.

Association of natural numbers with colours This functionality was needed in `LuliaP` where the esacpe number of the iterarion is associated with a colour.

```
/black{0 0 0 setrgbcolor}def .../yellow{1 1 0 setrgbcolor}% from PSLIB.eps
/colours{[/black .../yellow]}def
...                  %calculate escape number
colours k get cvx exec%k is escape number
```

The k*th* colour is now in use.

Fonts for free Don Lancaster in his `PSsecrets` gives many font variations.

[14] It is interesting to see the control points back as coefficients in the Bernsteĭn polynomial representation.

[15] Named after de Casteljau.

In practice I do not use this facility. I estimate the `BoundingBox` of a picture, reasonably. In the example it is a trifle.

2D pictures

Merging .eps pictures in .tex documents: flowchartTeXandPS

`.eps` pictures as such can't be included when processing with the TEX-engine pdfTEX, which I use in TEXworks. They first have to be converted into `.pdf`. They are more efficiently processed by TEXWorks when a priori converted into `.eps`.

MetaPost users prefer Hobby's `boxes` package for structure diagrams or flowcharts, I presume. I consider the use of straight PostScript equally simple or equally difficult, depending on your expertise.

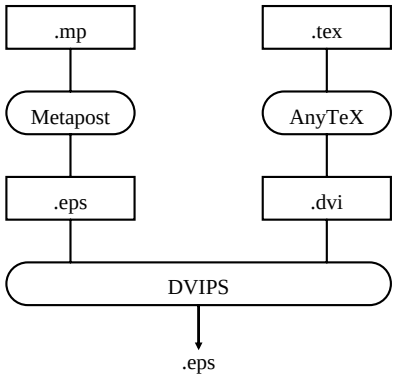
Compared with the old flowchart as given in *Just a lttle bit of PostScript*[16] the inclusion of pictures produced by PostScript in TEX documents has become simpler, thanks to pdfTEX and TEXworks. For the flowchart `diamondstroke` and `ovalstroke` have been written in analogy with PostScript's `rectstroke`, and of course they have been added to `PSlib.eps`. One can easily imagine packages where the elements can be dragged and dropped on a grid to build flowcharts. For simple flowcharts the PostScript operators will do.



Loop flowcharts: flowchartloop

The picture has been discussed and presented in *Recreational Use of TEX&Co*

[16] GKP picture lost alas after 20 years, so I programmed it anew in PostScript.

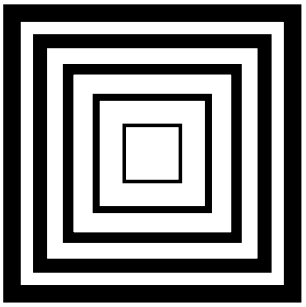
In MS Word and Nero (Version 10 with LightScribe) one can create labels interactively. LightScribe, a HP technique to burn labels on special discs as well, allows only for black and white labels.

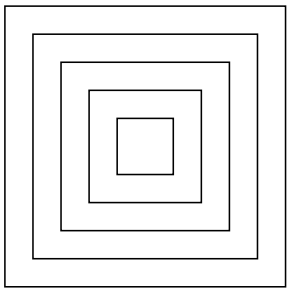
My wife, not at all a TEXie, designs labels in Photoshop and prints them on prefab glued paper by the tool CDFACE1.6 (Media labeling software templates for: CDs, DVDs, jewel cases, envelopes, floppy discs, audio cassettes, dat tapes, zip discs). The special tool CDFACE can handle all, no PhotoShop is needed.

Willi Egger has shown, MAPS 2009, how to use ConTEXt for the purpose.

Nest of squares. Blue book, P2 p131

A triviality? Not so in PostScript, because the scaling of user space also scales the `linewidth`.[17] The example shows how to program à la PostScript with invariant `linewidth`. Below, I also included the old procedural way of programming a nest of squares.





```
%!PS-Adobe-3.0  EPSF-3.0
%%Title: Nest of squares Adobe

Adobe's Blue book star, p51

Bogusław Jackowski taught NTG members in the early 90-ies Metafont and showed us how to draw a star, similar to Adobe. Using Metafont for graphics nowadays is not practical. MetaPost is used for the purpose, although the resulting PostScript is hard to read, and ipso facto to modify. I simplified Adobe's star by neglecting the `fill` cq `eofill`.

```
%!PS-Adobe-3.0  EPSF-3.0
%%Title: Star Adobe, Blue book p51
%%BoundingBox: -2 -45 73 28
%%BeginSetup
%%EndSetup
%%BeginProlog

Binary tree

In the TEXbook in the tables chapter, exc22.14, a binary tree has been used, implicitly. The production rule à la Lindenmayer for the balanced tree reads

$$\mathrm{Bt}_n = \mathrm{E}_n \oplus [\mathrm{N}_{n\div 2}\,\mathrm{Bt}_{n\div 2}] \oplus [\mathrm{S}_{n\div 2}\,\mathrm{Bt}_{n\div 2}], \quad \text{with} \quad n = \ldots 256, 128, \ldots 2,$$

Bt_n the Binary tree of order n,
E_n, N_n, S_n means draw East, North, South with step-size n
$\oplus$ means splice operator, i.e. concatenate properly,
[means store graphics state on the GS-stack and open a new one,
] means remove current graphics state off the Graphics State stack and recall previous.[18]

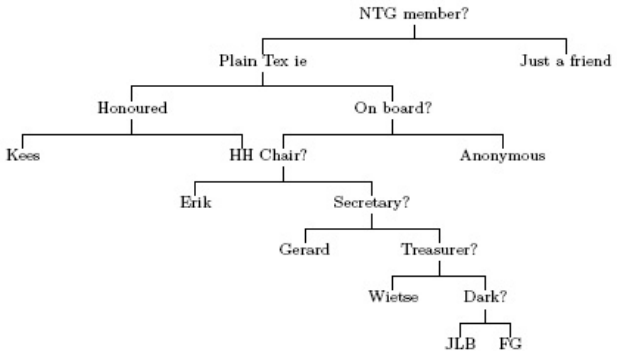
[18] The addition of the graphics state concept to the Lindenmayer production rules is an enrichment.

An unbalanced tree in TEX

```
\input blue.tex
\thisbt{\xoffset{-400}}
\beginbt 1 NTG member?
10 Plain Tex ie
100 Honoured
1000 Kees
1001 HH
101 On board?
1010 Chair?
10100 Erik
10101 Secretary?
101010 Gerard
101011 Treasurer?
1010110 Wietse
1010111 Dark?
10101110 JLB
10101111 FB
1011 Anonymous
11 Just a friend
\endbt
```



Below from `bttool` which comes with `BLUe.tex`, the backtrack macro has been copied. The nodes are binary numbers, and when the `node<binary number>` is undefined the end of the branch has been reached, and backtracking is performed. `\whiteS` draws South and the leaves. Pretty advanced macro writing. BLUe in full glory.

```
\beginbt \def\drawbt{\whiteS{120}%
   \ea\ifx\csname\node0\endcsname\relax
          \tbward\fi%Backtrack
   \S{80}\advance\k-125
   {\W{\the\k}\S{80}\edef\node{\node0}%
    \drawbt}%
    \E{\the\k}\S{80}\edef\node{\node1}%
    \drawbt\relax}
\def\tbward#1\relax{\fi}
```

Note the minimal, necessary data specifications: just the binary 'addresses' of the nodes next to their contents. TEX will handle all that is needed.

Trinary Tree

One might add another branch to a binary tree and create trinary trees.

```

Sierpiński's sieve

is related to a trinary tree, and constructed by deleting the inner 'half-triangles', which are obtained by connecting the midpoints of the sides, recursively ad infinitum.

A recursive variant is similar to the coding and production rule of the Pythagoras Tree: draw a collection of isosceles triangles, properly placed and scaled. More concrete. The order 1 is an isosceles triangle with side s, of which I assumed the left corner in (0,0). The order 2 is a triangle of order 1 where scaled triangles at the sides are added. Repeat this process of placing scaled isosceles triangles for each new triangle.

Sierpiński triangle by Iterated Function System

A rather unusual way to generate the Sierpiński sieve is by the functions, L, R, T, given below, each applied with equal probability, Lauwerier(1990, p34).

$$\begin{pmatrix} x' \\ y' \end{pmatrix} \stackrel{\text{L}}{=} .5 \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + .5 \begin{pmatrix} -1 \\ -1 \end{pmatrix} \; ; \; \begin{pmatrix} x' \\ y' \end{pmatrix} \stackrel{\text{R}}{=} .5 \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + .5 \begin{pmatrix} 1 \\ -1 \end{pmatrix} \; ; \; \begin{pmatrix} x' \\ y' \end{pmatrix} \stackrel{\text{T}}{=} .5 \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + .5 \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

Randomized Sierpiński triangle

Peitgen c.s.(2004) mentions the addition of randomness to the Sierpiński triangle. Nice.

Pascal triangle and Sierpiński triangle

Pascal's triangle gives the binomial coefficients for the sum representation of $(1+x)^n = \sum_{k=0}^{n} \binom{n}{k} x^k, n \geq 0$. In PWT(1995) for low n Pascal's triangle was obtained by TEX alone simply by.

```
$$\displaylines{1\cr
  1\quad1\cr
  1\quad2\quad1\cr
  1\quad3\quad3\quad1\cr}$$
```

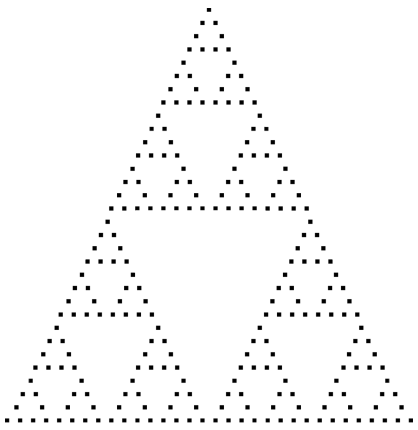
$$\begin{array}{c} 1 \\ 1 \quad 1 \\ 1 \quad 2 \quad 1 \\ 1 \quad 3 \quad 3 \quad 1 \end{array}$$

For general order n the macro for the Pascal triangle were the entries are calculated by the recursion $\binom{n}{k} = \binom{n-1}{k} + \binom{n-1}{k-1}, n \geq k \geq 1$, given in PWT reads

```
\newcount\n \newcount\rcnt \newcount\ccnt \newcount\tableentry \newcount\prev
%
\def\pascal#1{\n#1 \def\0{1} \ccnt1
   \loop\ea\xdef\csname\the\ccnt\endcsname{0} \ifnum\ccnt<\n \advance\ccnt1\repeat                    %auxiliary sentinels
   \rcnt0 \ccnt0 \displaylines{\rows}}
%
\def\rows{\global\advance\rcnt1 \ifnum\rcnt>\n \swor\fi \nxtrow\rows} \def\swor#1\rows{\fi}
%
```

```
\def\nxtrow{1 \ccnt1 \prev1
 \loop\ifnum\ccnt<\rcnt \tableentry\prev \prev\csname\the\ccnt\endcsname \advance\tableentry\prev           %recursive addition
  \ea\xdef\csname\the\ccnt\endcsname{\the\tableentry}%store the new entry
  \quad\the\tableentry \advance\ccnt1               %show the entry
 \repeat\cr}
```

Peitgen c.s.(2004) mentions the relationship between the Sierpiński triangle and the PASCAL triangle, when odd entries are blackened. Intriguing. Adaptation of the above code for the purpose is not that difficult.



```
\newcount\n \newcount\rcnt \newcount\ccnt \newcount\tableentry \newcount\prev
\def\pascal#1{\n#1 \def\0{1} \ccnt1
   \loop\ea\xdef\csname\the\ccnt\endcsname{0}              %auxiliary sentinel
   \ifnum\ccnt<\n \advance\ccnt1\repeat
   \rcnt0 \ccnt0 \displaylines{\rows}}

```

Pythagoras Tree

Much similar to Adobe's fractal arrow and my H-fractal. It is all about printing squares at the appropriate place and appropriately scaled.

The production rule for a Pythagoras Tree of order n reads

$$P_n = \square_s \oplus [T_{(0,s)} R^{45} S_{(\frac{1}{\sqrt{2}},\frac{1}{\sqrt{2}})} P_{n-1}] \oplus [T_{(\frac{s}{2},\frac{3s}{2})} R^{-45} S_{(\frac{1}{\sqrt{2}},\frac{1}{\sqrt{2}})} P_{n-1}],$$

with P_n the Pythagoras Tree of order n, $\oplus$ denotes splice operator, means add properly, [means store graphics state and open a new one,] means close current graphics state and recall previous, R^{45} means rotate US 45° in the PS sense, $S_{a,b}$ means scale US by a and b, $T_{a,b}$ means translate US by a and b, $\square_s$ means draw square with side s. In the Lindenmayer system [means start a new branch, remotely similar to a new graphics state or recursion level.

```

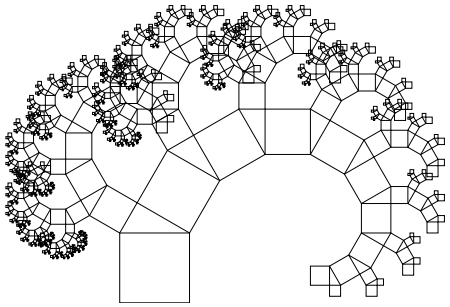
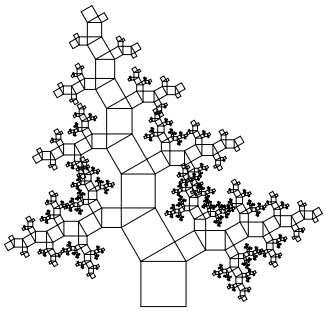
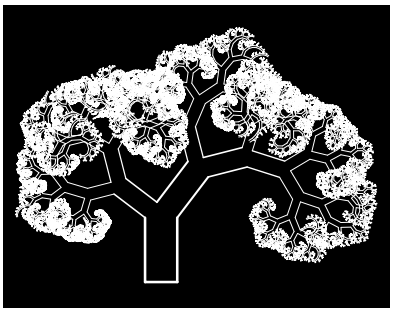
Variants







Cantor dust

The PostScript code for Cantor Dust of order n has a similar production rule as for the von Koch fractal

$$CD_n = [S_{\frac{1}{3}1} CD_{n-1}] \oplus [S_{\frac{1}{3}1}\, T_{2s\,0}\, CD_{n-1}]$$

with CD_0 the initial line, CD_n the Cantor Dust of order n, $\oplus$ splice operator, meaning add properly the second piece to the set, [open a new GS on the GS stack,] remove current graphics state from the GS stack and recall previous, $S_{a,b}$ means scale US by a and b, in x- and y-direction, $T_{a,b}$ means translate US by a and b, in x- and y-direction.

```

The 'fixed point' of the production rule is the Cantor Dust fractal. For just showing a few approximations of the Cantor Dust the TEX code will do. Lauwerier(1987) provides a tiny BASIC program `KAM`. He also associates the Cantor dust with the trinary number system, because the interval is divided into 3 pieces, repeatedly. The Cantor dust of [0, 1] consists of the trinary fractions where only the digits 0 and 2 occur, Lauwerier(1987, p26).

Cantor Dust as Iterated Function System by Lauwerier(1989, ch8)

$$x_{n+1} \overset{\text{L}}{=} x_n/3 \qquad \text{and} \qquad x_{n+1} \overset{\text{R}}{=} x_n/3 + 2/3 \qquad n = 0, 1, 2, \ldots \quad x_0 = 1/3.$$

His tiny BASIC program and my PostScript conversion read

```
X=.3         'start
FOR K=1 TO 100
   IF RND<.5 THEN X=X/3 ELSE X=(X+2)/3
   PSET(X, 0)'scale X if wanted
NEXT K
END
```

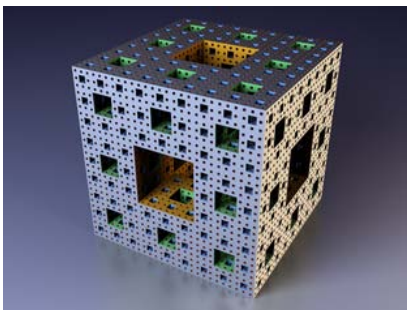
Cantor dust 2D, also called Sierpiński carpet

The algorithm reads: divide a square in 3^2 equal sub-squares and delete the middle, or the middle cross, and do this repeatedly for the remaining 8 squares.

At the EuroTEX95 Bogusław Jackowski showed his variant, probably in connection with his `mftoeps` program, which transforms Metafont code into PostScript.

In Metafont my program of old

```
tracingstats:=1;proofing:=1;screenstrokes; %
pickup pencircle scaled 1;
def sierpinskisquare (expr s, p)=
if s>5:unfill unitsquare scaled .333s
      shifted (p+.333s*(1,1));
   sierpinskisquare(.333s, p);
   sierpinskisquare(.333s, p+(.333s,0));
   sierpinskisquare(.333s, p+(.667s,0));
   sierpinskisquare(.333s, p+(0,.333s));
   sierpinskisquare(.333s, p+(0,.6673s));
   sierpinskisquare(.333s, p+(.667s,.333s));
   sierpinskisquare(.333s, p+(.667s,.667s));
   sierpinskisquare(.333s, p+(.333s,.667s));
fi enddef;
%
s=100; fill unitsquare scaled s;
sierpinskisquare(s,origin);
showit;
end
```



In TEX my coding of the 90-ies, which is included in `pic.dat`

```

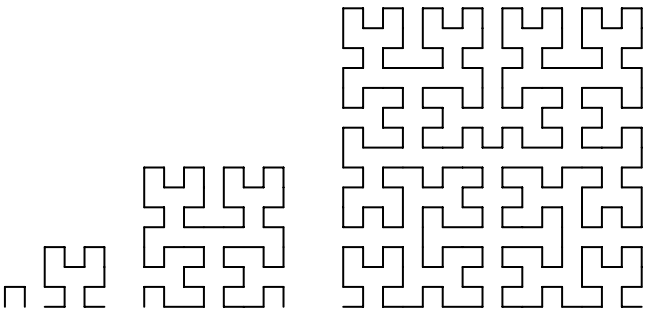
Hilbert curve

Wirth(1975) I consider a starting point for programming a Hilbert curve. The production rule of the Hilbert curve[19]

$$H_i = {}_mH_{i-1}^{90} \oplus \uparrow \oplus H_{i-1} \oplus \rightarrow \oplus H_{i-1} \oplus \downarrow \oplus {}_mH_{i-1}^{-90}, \quad \text{for } i = 1, 2, \ldots$$

where $\oplus$ means spliced, the superscript denotes the rotation angle, the arrows $\uparrow \rightarrow \downarrow$ mean draw a segment in the direction North, East, and South. In order to splice correctly, the rotated copies have also to be mirrored, which is indicated by the pre-index m.



```

Lauwerier(1990) provides a BASIC program, `Peanol`, for the Hilbert curves, restricted to orders ≤ 5, via the Turtle Graphics method, i.e. drawing forward, meaning the broken line is obtained by drawing the segments in increasing order 1, 2, 3, ... The above program draws also forward by backtracking, a short of LIFO, Last-In-First-Out. In `Peanol` the direction numbers are stored in an array of size 3411. Large enough for practical purposes. (The program above does not need the explicit direction numbers.) For Wirth's(1975) program see *Classical Math fractals in PostScript*.

[19] The 'fixed-point' of the production rule is the real fractal.

Hilbert curve in Metafont and Joseph Romanovski's (1995) PostScript code

Sierpiński islands

Wirth(1975) I consider a starting point for programming a Sierpiński island.

The curve is closed and is composed of 4 (90° rotated) broken lines connected by lines in the direction SE, SW, NW and NE. The program consists of 2 parts: first the generation of a side and second the appropriate splicing of rotated copies.

The production rule for a side

$$S_i = S_{i-1} \oplus SE \oplus S_{i-1}^{-90} \oplus E \oplus S_{i-1}^{90} \oplus NE \oplus S_{i-1}, \quad \text{for } i = 1, 2, \ldots$$

where $\oplus$ means spliced, the superscript denotes the rotation angle. and `SE`, `E`, `NE` mean draw a line in the direction South-East, East, and North-East.

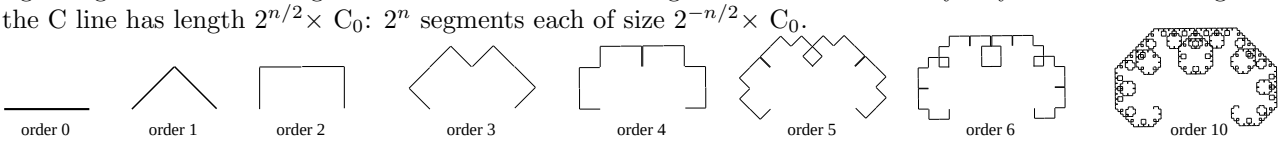
Lévy fractal

An approximation of the Lévy fractal is also called a C (broken) line of a certain order. The constructive definition of various orders of C lines starts with a straight line, let us call this line C_0. An isosceles triangle with angles 45°, 90° and 45° is built on this line as hypotenuse. The original line is then replaced by the other two sides of this triangle to obtain C_1. Next, the two new lines each form the base for another right-angled isosceles triangle, and are replaced by the other two sides of their respective triangle, to obtain C_2. After two steps, the broken line has taken the appearance of three sides of a rectangle of twice the length of the original line. At each subsequent stage, each segment in the C figure is replaced by the other two sides of a right-angled isosceles triangle built on it. Such a rewriting relates to a Lindenmayer system. After n stages the C line has length $2^{n/2}\times$ C_0: 2^n segments each of size $2^{-n/2}\times$ C_0.



Production rule

$$C_n = [R_{45}S_{(\frac{1}{\sqrt{2}},\frac{1}{\sqrt{2}})}C_{n-1}] \oplus T_{\frac{s}{2}\frac{s}{2}}\,[R_{-45}S_{(\frac{1}{\sqrt{2}},\frac{1}{\sqrt{2}})}C_{n-1}], \quad \text{with} \quad C_0 = \text{initial line, and}$$

C_n the Lévy C curve of order n, $\oplus$ splice operator, meaning add properly, i.e. $T_{(\frac{s}{2},\frac{s}{2})}$, [means store graphics state on the GS stack and open a new one,] means remove current graphics state off the GS stack and recall previous, R_{45} means rotate US 45° in the PS sense $S_{a,b}$ means scale US by a and b, in x- and y-direction $T_{a,b}$ means translate US by a and b, in x- and y-direction.

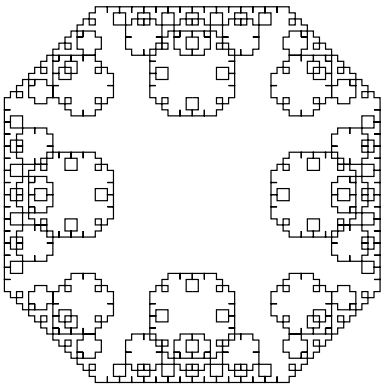
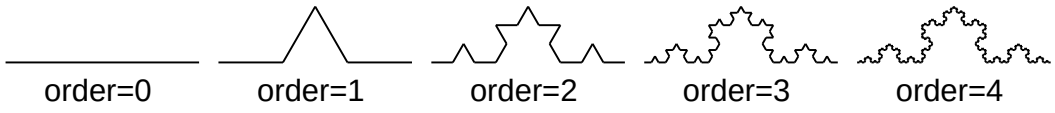
Lévy carpet. C_{10} spliced with its `-1 1 scaled` copy, a Lévy carpet.



von Koch fractal

A von Koch broken line and a Lévy C line are related to a Lindenmayer system, also called a rewrite system. For the von Koch broken line the rewrite is: divide a line in 3 pieces and replace the middle piece by an equilateral triangle, with the base omitted. Repeat the process on the 4 line pieces to the required order. It is similar to the defining construction process of the Lévy fractal; the result conveys a different impression, however. Below $K_0 \ldots K_4$, scaled with increasing order (line thickness is scaled as well).



Lindemayer production rule enriched with PostScript concepts for the von Koch fractal

$$K_n = [S_{\frac{1}{3}\frac{1}{3}} K_{n-1}] \oplus T_{\frac{s}{3}0} [S_{\frac{1}{3}\frac{1}{3}} R_{60} K_{n-1}] \oplus T_{\frac{s}{6}\frac{s\sqrt{3}}{6}} [S_{\frac{1}{3}\frac{1}{3}} R_{-60} K_{n-1}] \oplus T_{\frac{s}{6}\frac{-s\sqrt{3}}{6}} [S_{\frac{1}{3}\frac{1}{3}} K_{n-1}]$$

with, K_0 the initial line, K_n the von Koch curve of order n, $\oplus$ splice operator, meaning add properly, i.e. translate, [open a new GS on the GS stack,] remove current graphics state from the GS stack and recall previous, R_{60} means rotate US 60° in the PS sense, $S_{a,b}$ means scale US by a and b, in x- and y-direction $T_{a,b}$ means translate US by a and b, in x- and y-direction.

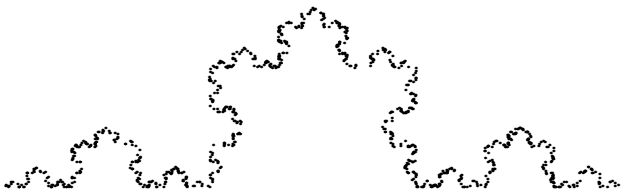
Von Koch-like fractal as Iterated Function System

Lauwerier(1994) in one of his exercises created a von Koch-like fractal by Iterated Function Systems, which consists of 2 contracted, affine transformations, L and R, which both for the von Koch fractal do contraction and mirroring.



$$\begin{pmatrix} x' \\ y' \end{pmatrix} \overset{\text{L}}{=} \begin{pmatrix} .5 & .289 \\ .289 & -.5 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} -.5 \\ .289 \end{pmatrix} \text{ and } \begin{pmatrix} x' \\ y' \end{pmatrix} \overset{\text{R}}{=} \begin{pmatrix} .5 & -.289 \\ -.289 & -.5 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} .5 \\ .289 \end{pmatrix}$$

Associated with the von Koch fractal are 2 rotations with mirroring with centres for L: (-1,0) and for R: (1,0) and contraction $\sqrt{.5^2 + .289^2} \approx .58$. Amazing, isn't it! Laurier's BASIC program `FRACMC4` and my transcription are given below. (MC is abbreviation for Monte Carlo, meaning alternate L and R by gambling.)

```
REM ***iteratief systeem, 2 spiegelingen, FRACMC4***

Julia fractals

The Julia set for $z_i = z_{i-1}^2 + c, \quad i = 1, 2, 3, \ldots$ is a repeller; the Julia set for the inverse iteration is an attractor. `JULIAMC` implements inverse iteration. The parameters of the `JULIAMC` are: the real and imaginary part of the problem parameter `c`, i.e. `a` and `b`, and the number of points of the fractal to be generated, `n`. It is the simplest Julia fractal generator.

$$z_i = z_{i-1}^2 + c, \quad i = 1, 2, 3, \ldots \qquad \rightarrow \qquad \text{Inverse:} \quad z_{i-1} = \pm\sqrt{z_i - c}, \quad i = n+10, \ldots\ , 1, \quad |z_{n+10}| <= 1.$$

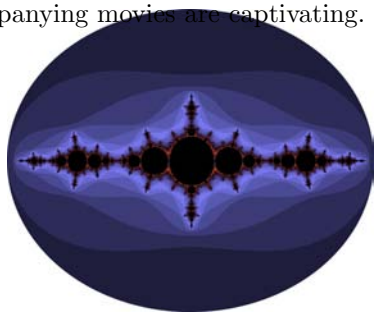
PSlib.eps contains moreover `def`s `JULIABS`, which implements the boundary scan method, `JULIAF`, which generates a filled fractal, `JULIAP`, which implements the pixel method, `JULIAD`, which is based on the distance formula.

`Chaos` and `Fractalus` are packages, in the Public Domain, which create fractals with rich colour possibilities. The aqccompanying movies are captivating.



Julia fractals II: San Marco

The Boundary Scan method yields a more complete fractal. Implicit is that the BoundingBox is a factor 100 the domain of the fractal.

Circle symmetric Julia fractals I

The dynamical system used by Field c.s. in `JULIAS` for an m-fold rotation symmetric pseudo-Julia fractal reads, Lauwerier(1996, p129)

$$z_{n+1} = z_n(a + b/z_n^m + c)) \quad \text{with} \quad 1 = a + b/(1 + c).$$

The parameters are `a`, `b`, `N` the number of points, `kmax`, the maximum number of iterations per grid point.

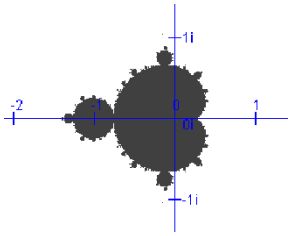
Mandelbrot's first M-fractal

Mandelbrot in 1980 answered the question:

For which values of c will the Julia fractal, J(c), be line-like and for which values dust-like?

He was surprised, but ... realized the relevance.

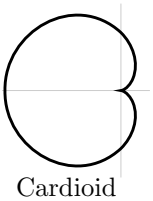


Form and size of M-fractal

Mandelbrot also elaborated on the fractal dimension notion. The M-fractal curve, and surface, have fractal dimension D=2.

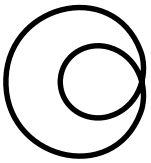
M-cardiod

A Cardioid is defined in polar coordinates by $r = 2a(1 + \cos\theta)$, $\theta \in [0,2\pi]$. A version of the more general Limaçon, with parameter b=.25, $r = 2a(b + \cos\theta)$, $\theta \in [0,2\pi]$ is included at right.



Cardioid

```
%!PS-Adobe-3.0 EPSF-3.0
%%Title: Cardioid in Polar Coordinates
%%BoundingBox: 0-30 -41 30
%%BeginSetup
%%EndSetup
/t 0 def /2a -20 def 2 2a mul 0 moveto
120{3 rotate /t t 3 add def
    2a 1 t cos add mul 0 lineto}repeat
stroke showpage
```



Limaçon

The equations for the cardioid in Cartesian coordinates, parametric in $\varphi \in [0, 2\pi]$, read

$$x = \cos(\varphi)/2 - \cos(2\varphi)/4$$
$$y = \sin(\varphi)/2 - \sin(2\varphi)/4$$

The cardioid has been draw, with the main circle centre at (-1,0) and radius .25, next to it; see accompanying picture. The cardioid is of the same size as the M-fractal cardioid.

In order to have an idea of the scale in the M-fractal picture the relevant numbers are shown underneath the drawing. The a- and b-axis have been drawn dashed.

If $|4a^2 + 8a + b^2| < 3.75$ then (a,b) lies inside the cardioid.

If $|a + ib + 1| < .25$ then (a,b) lies inside the circle.

Lauwerier(1995) contains a BASIC program for drawing a cardiod, `CARDIO`.

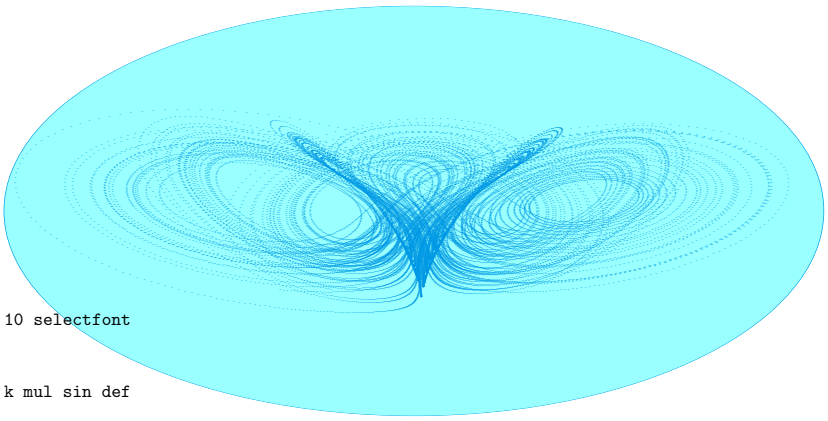
Lorenz attractor

Lorenz simplified the differential equations for weather forecasting, and stumbled upun the strange attractor for the difference equations. Interactive BASIC shows the growth of the data, while in batch PostScript we only see the results, alas. What we want to know from a given sequence whether they come from an attractor, and if so, we also need to quatify this attractor in terms of Lyapunov exponents and dimension so that we may speak of a chaotic and strange attractor.

The shape of the Lorentz attractor gave rise to the name butterfly-effect.



```

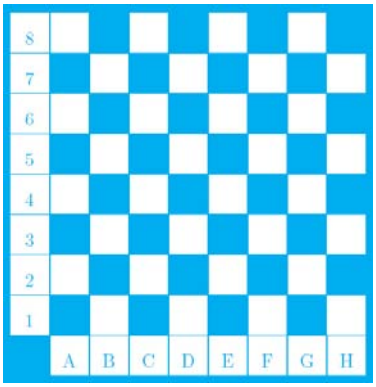
My programming of the chessboard goes via my crosswords macros.

```
\begincrosswords
\obeyspaces\let =\space\csize=3ex
\bdata
8 * * * *
7* * * *
6 * * * *
5* * * *
4 * * * *
3* * * *
2 * * * *
1* * * *
*ABCDEFGH
\edata
\sol
\endcrosswords
```



Of course it is easier just to put black and white boxes next to each other. I had the `crosswords` environment at hand and misused it for the purpose.

Crosswords

Typesetting Crosswords via TEX, MAPS 8, 1992

The typesetting crosswords tool, as one of the tools in `tools.dat`, comes with `BLUe.tex`. The environment is `\begincrosswords` ... `\endcrosswords`. The example has been borrowed from the table chapter of PWT. The crosswords tool has been copied from BLUe's `tools.dat` and used stand-alone in this paper.

*n*S
Edit
\edata
\crw
<Clues in 2 \vtop's, v-centered>
\sol
\endcrosswords
```

Interesting is the near-WYSIWYG-data specification of the puzzle. Minimal mark-up has been strived after, no `\cr`-s nor `&`-s have to be inserted by the user, TEX will do it for you. Mean-and-lean is that the solution or the puzzle can be toggled by `\sol` respectively `\crw`. Note the use of capitals and lower case. The capitals mark where a number for the clues has to be inserted, automagically ☺. Paradigm: let TEX insert mark-up.

The above variant via PostScript inspired by David Byram–Wigfield,[20] who created a special font `QuadFont`, unnecessary, but interesting in itself, for the black and white squares. But ... without numbers for the clues and no toggling of solution and puzzle. In my PostScript version I simplified, without creating opr using `QuadFont`. TEX's version I consider superior.

[20] For a wealth of examples see Practical PostScript—A guide to Digital Typesetting. David Byram–Wigfield. `http://www.cappella.demon.co.uk`, or John Deubert's `http://www.acumentraining.com/acumenjournal.html`.

Adobe Systems

Interesting use of `oshow`.

I imitated Voß' example of rotated `A`'s, more-or-less, as variant of Adobe's rotated word `Adobe`, Blue book p98. Vo31' picture has also been supplied in the LaTeX Graphics Companion p357.[21]

In `PSTricks`' code is too much one has to remember to my taste, too many and too varied braces, {...} , (...), and [...] ... moreover, the data `A` has to be supplied three times. Personally, I abhor the (curly) braces mania, and favour minimal mark-up; providing the data `A` three times is not minimal.

Spirals: Archimedian and Growth

The Archimedes Spiral is in polar coordinates defined by $r_\theta = k\theta, \quad 0 \leq \theta < \infty$.

The Growth Spiral is in polar coordinates defined by $\ln r_\theta = k\theta$ or $r_\theta = \mathrm{e}^{k\theta}, \quad -\infty < \theta < \infty$.

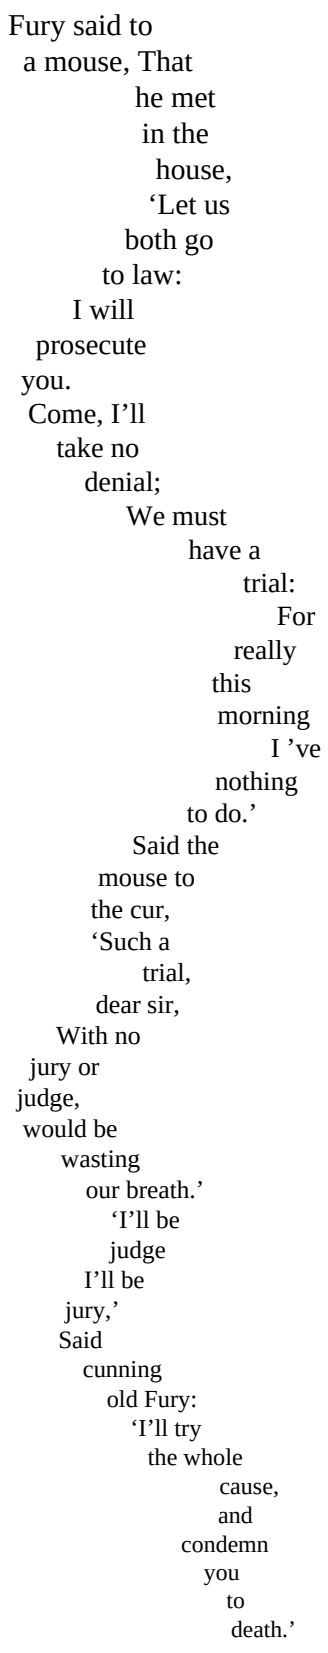
The mouse's tail and Alice's tale



This emblematic proza by Lewis Carroll is typeset in PostScript by the use of `forall`, which expects an array, enclosed by [ ], and a procedure enclosed by { } on the stack. The array contains a necklage of strings, each enclosed by ( ), which holds the WYSIWYG data. The procedure scales and typesets the lines. No explicit positioning by coordinates on the page nor controlling of the loop is needed.

Metaposttcode adapted from the old Metafont code.

```
beginfig(0);
size:=210; path p[];
p1=(-1.1size, -1.5size){right}---(-.9size, -1.49size)..(-.7size,-1.1size)..(-.4size,-.9size)..
(-.4size, -.3size)..(-.1size,0)..(-.5size,.6size)..(-.55size,1.2size)...{left(-1.1size,1.5size)---cycle;
p2=p1 reflectedabout((0,-size), (0,size));
fill p1; fill p2;
draw (-1.2size, -1.6size)---(1.2size,-1.6size)---(1.2size,1.6size)---(-1.2size,1.6size)---cycle;
endfig;
```

The .eps code was obtained from Metapost, with the frame added in PostScript.

Malevich's White cross on a white background

Malevich Suprematism:
White cross on a White background
Emulation →

I have included a picture, and its emulation, of Malevich's[23] 'White Cross on a white background,' because he is the father of suprematism, which deletes the superfluous, which I associate with Minimal Mark-up. But ... sometimes redundancy is beneficial.

In Metafont the following Vasarely's I programmed 20 years ago. Interesting is the use of `interpath`, similar as used in the heart figure in the Metafont book p134. `interpath` is not available in PostScript, because we don't have explicit paths. Below I have imitated `interpath` functionality in PostScript for this simple example. No path data structure nor picture datastructure. Just transformation of User Space. Compare the code with the Metapost code given in Recreational use of TEX&Co. Simpler to read isn't it? The code of the right picture resembles much the code of Schrofer and is supplied in `PSlib.eps` under the name `vasarelybloks`.

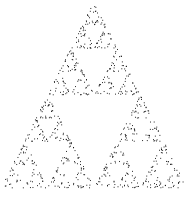
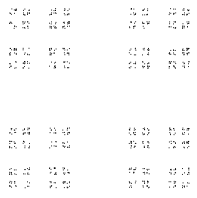
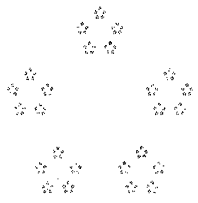
IFS in TEX

In 1989 I attended the TUG conference where Alan Hoenig showed some Iterated Function System fractals, a miracle,[24] which I reproduced in PWT. The idea is that the points within an n-gon are created by: the mean of a random point within the n-gon and one of its corners at random, à la Monte Carlo. A random number generator for plain TEX had to be written. The representation of the corner points is tricky via `\newdimen`-variables, in order to perform the arithmetic. Too many details in order to be presented here. The code for the three Sierpiński carpets below is included in `pic.dat`, which comes with `Blue.tex`







[24] His paper has been published in TUGboat 1989. For Iterated Function Systems and Fractals, see Peitgen c.s. (2004 2nd ed): Chaos and Fractals. Springer, which is more accessible than Barnsley, because . no sophisticated Math is required for reading the Peitgen book.

Escher doughnut

The doughnut was programmed in declarative Metafont. On occasion of EuroTEX2012 the code was processed by Metapost and a PostScript version emerged by editing the PostScript code. How to program this doughnut from scratch in PostScript is not clear to me. What makes it hard are the hidden lines.

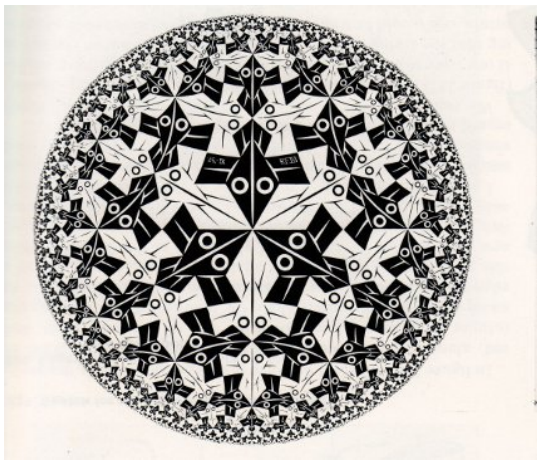
Coxeter cooperated with Escher.

The figure left from Coxeter stimulated Escher to develop his limit circle series. At reight Eschers limcircleI.



Escher‘s Circle limit III grid

Coxeter’s solution

Coxeter, in *What Escher left unstated*, The Mathematical Intelligences, 18, 4, 1996, analyzed Escher’s Circle Limit III. He started from the rotational symmetry at P and derived (the parameters for) the grid.

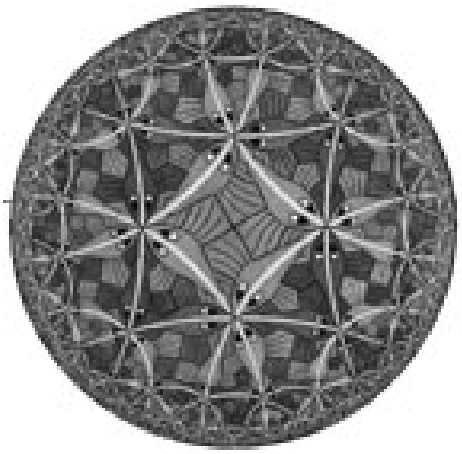
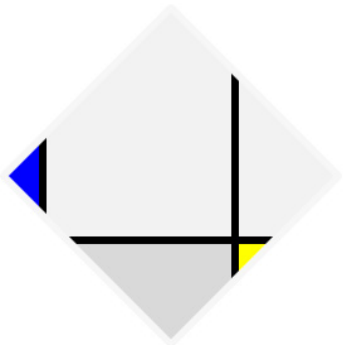
At right Eschers Limit Circle III



Invitation

In the 90-ties I worked in Metafont, and reused the code for processing with Metapost much later. Mondriaan missed the near golden ratio proportions. The pictures included adhere to the golden ratio proportions. Later I programmed `intersection` for the calculation of the intersection points of 2 straight lines directly in PostScript, no need to use Metapost. The PostScript and Metapost programs are equal modulo some syntactic sugar. In rewriting the Metapost code into PostScript I realized that the calculation of the intersection point is superfluous.

```
%Mondriaan-like Lozenge with 3 lines. Fall 2009 kisa1@xs4all.nl
beginfig(0)
s=200;
z1=(0,.5s); z2=(.5s,s); z3=(s,.5s); z4=(.5s,0);
z5=0.618/1.618[z2,z3]; z6=0.618/1.618[z3,z4];
z7= 1/1.618[z3,z4]; z8=1/1.618[z4,z1];
z9=0.382/1.618[z1,z4]; z10=0.382/1.618[z1,z2];
z11= (z5--z7) intersectionpoint (z6--z8);
path p; p = z1--z2--z3--z4--cycle;
pw=4; pickup pencircle scaled pw;
fill p withcolor .95white;
fill z1--z10--z9--cycle withcolor blue;
fill z7--z11--z6--cycle withcolor red+green;
fill z8--z11--z7--z4--cycle withcolor .85white;
draw z5--z7;
draw z6--z8;
draw z9--z10;
clip currentpicture  to p;
draw p withcolor .97white;
endfig
end
```



Made into an invitation by Photoshop and the recent developed direct PostScript

Note the use of the library `def intersect`.

Game of Life

Lauwerier(1990) mentions a fractal, which he obtained from the Pickover variant of the Game of Life, made popular by Martin Gardner in a Scientific American of 1970. The game is played on a grid. Each node can be alive or dead. Once alive it stays alive. If dead it comes to life if only one neighbour, N, E, S or W is alive. On each heartbeat the whole grid is inspected in parallel.

I simplified Lauwerier's BASIC program by inspecting on each heartbeat only the new contra diagonals ($i + j$ =constant) in the first quadrant.

Line inversion

The inversion of a line in a circle is a circle through the origin of the inversion circle. The picture is a nice illustration of the theorem. The use of angle marks contributes much to the clarity of the picture.

Inversion of straight line pieces

Three squares with sides r, 2r , 4r centred around the origin are inverted in the (dashed) circle $I_{r,(0,0)}$. The inversions are drawn in the same picture non-dashed and bold. The right figure is the complement: the inversions of the lines with the sides of the squares left out.

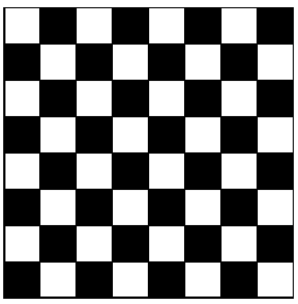
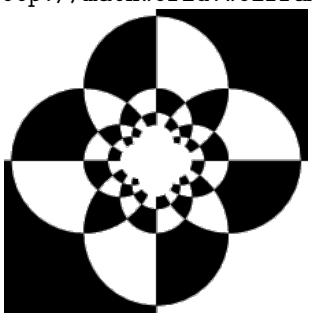
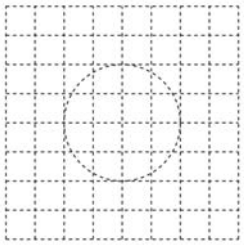
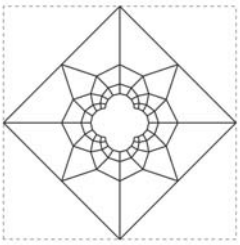
A beautiful illustration of the inversion of line pieces is the inversion of a chessboard centred at (0, 0) in a small circle also centred at (0, 0) (M. Gardner 1984, pp. 244-245; R. Dixon 1991). In the picture below the chessboard and its inversion are shown, borrowed from `http://mathworld.wolfram.com/Inversion.html`.





Circle inversion of a rectangular grid





The inversion has been simplified: circular curves have been straightened in the inversion.

At right the realization as a skylight window.

The first picture from the left shows the grid and the inversion circle. The second picture shows the inversion of the grid. At right the resulting stainless glass skylight window, size 60x60cm, to decorate our apartment in Chisinau.

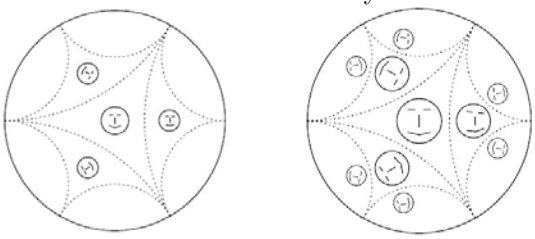
Inversion of a smiley pattern

can be done by use of the PostScript operator `pathforall`. This operator appends to the current path. It is not straightforward how to stroke the path created by `pathforall`, separately. I call the used technique[25] partial delayed execution, which can be useful as shown in this case. The pattern is inverted in two parts: eyes, nose and mouth by `pathforall` and the circumference by `circleinversion`.



In the right picture, with 2^{nd} level inversions, the operators `pointinversion` and `circleinversion` are invoked repeatedly: the invoke for the 1^{st} level inversion is immediately followed by the invoke for the 2^{nd} level inversion in the procedures for `pathforall`.

PS code with 1^{st} level inversions only. It demonstrates how to use fruitfully `pathforall`.

```

Any two disjunct circles can be made concentric

by inversion by picking the inversion centre as one of the so-called limiting points.
`http://mathworld.wolfram.com/LimitingPoint.html`.

The dashed circle is the inversion circle I with abscissa of the centre $\mathrm{I}_{rR} = \frac{l \pm \sqrt{l^2 - 4d^2R^2}}{2d}$ with $l = d^2 - r^2 + R^2$. The main circle is $C_{R,(0,0)}$ and the small circle $C_{r,(d,0)}$. The radius of the inversion circle determines the size of the concentric circles. `http://mathworld.wolfram.com/ConcentricCircles.html`.

An ill-posed subproblem —touching point of 2 circles—has been reformulated in a well-posed problem.

Apollonius problem

Given three disjunct circles find the circles touching the circles. In *Circle Inversion* the problem has been solved and all 8 solutions have been programmed in MetaPost and PostScript. A universal PostScript definition `apollonius` has emerged. The definition for a slight variant for the case when one given circle contains the two other ones is called `apollonius2`. The inversion method for solving Apollonius problem has also been explained and illustrated in the article.

Dodecaeder

Borrowed from Lauwerier(1987): Meetkunde met de microcomputer. The formula for the cornerpoints are nice and symmetric. Unfortunately each coordinate can't be scaled for a reazonable sized picture. I kludged around. For the number of cornerpoints, H, the number of sides, S, and the number of ribs, R, there exists the relation: H+S=R+2. Wikipedia contains interesting data.

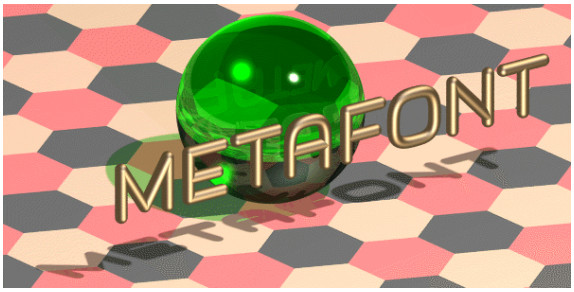
Jacko's Toruń98 logo.

The above is my best mimic in PostScript of Jackowski's Toruń98 dynamic masterpiece logo.

Metafont&TEX can be used to create beautiful artistic results with fonts.

This has been shown in the 90-ies by Bogusław Jackowski and Marek Ryćko. Non-scalability is not relevant for pieces of art.



I could not reproduce these TEX-Metafont pictures in PostScript. Maybe the TEXnique has become outdated in view of the OpenTypeFonts activity. A challenge for the reader to realize this with OTFs?

Toroid

Lauwerier in *Meetkunde met de microcomputer* explained and demonstrated the picture.

Emulation Gabo's Torsion

The construction, a stringed metal frame, consists essentially of 2 identical rectangular isosceles triangles, with a curved hypotenuse and curved inner sides, on top of each other, with the upper triangle turned upside down and rotated over 90°. The inner curves of the lower triangle are connected by lines to the inner curves of the upper triangle, the strings of the object. Cap and cup have horizontal strings. The stringing yields what I call stringed surfaces. The spline data on the triangles of the object are important and shown in the accompanying figures.

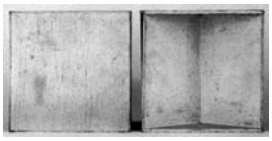
Emulation Gabo's Spheric Theme

Spheric Themes demonstrate another way of how Gabo constructed (the idea of) surfaces: by planes orthogonal to the surface. He called it the stereometric method of representing surfaces.

Stereometry is a branch of mathematics concerned with the description of 3D objects and calculations related to these. For Gabo a cube is not represented by its 6 surfaces, but by top, bottom, and the intersecting diagonal planes, making the inside visible



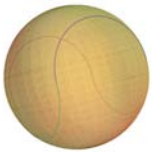
Famous are his constructed head series, such as the earlier shown `Head in a Corner Niche`, and the `Head ...` on the book cover. In the Spheric Theme we are about to emulate both ways of representing surfaces: stereometric and stringed surfaces are integrated in one object.

Gabo invented how to model his Spheric Theme curves:

> 'The basic form was made by taking two identical flat pierced circles or broad rings and making a single cut in each along the line of a radius. The two discs are bent in a serpentine curve and butt-jointed to each other at both ends. The resulting figure fits exactly into a sphere and the outer edges of the discs form the interlocking curves like those that divide the pieces of felt covering the tennis ball.'

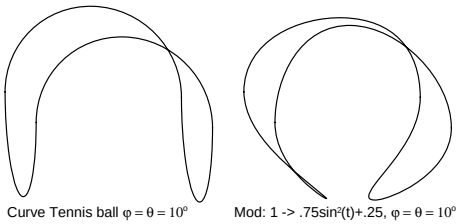
Frame of Spheric Theme

The outer circumference of the frame is the curve on the tennis ball, a little deformed. The four parts of the tennis ball curve are given by the formulas



$$\{(x,y,z)|(1,\sin t,\cos t)\}$$
$$\{(x,y,z)|(-1,\sin t,\cos t)\}$$
$$\{(x,y,z)|(-\sin t,1,-\cos t)\}$$
$$\{(x,y,z)|(-1,-\sin t,-\cos t)\}$$

$$t\in(-\frac{\pi}{2},\frac{\pi}{2})$$



I modified the tennis ball curve by the deformation $1 \to (1-d)\sin^2 t + d$, $d = .25$, which comes close to Gabo's. For the inner circumference I took the outer scaled by a factor 3.

Emulation of Gabo's Linear Construction in Space Suspended

Linear Construction in Space Suspended is one of Gabo's favorites, which he used to display on retrospective exhibitions.

The object consists of 2 identical, 'triangular' slabs of clear plastic orthogonal (rotated and mirrored) to each other, wired, and suspended on a metal arc with a wooden base.

What motivated Gabo to create just these triangular shapes? What were the restrictions? Did the balance of the object play a role, in choosing the rotation symmetry axes? I don't think so, just his feeling for beauty, I guess. The unbalance creates tension.

The frame part in the yz plane is realized by 2 splines: `a0 moveto a1 a2 a3 curveto a5 a5 a7 curveto closepath`. For the first B-cubic the data points are a_0, a_3 with control points a_1, a_2. For the second B-cubic the data points are a_3, a_7 with control points a_5, a_6; not critical. The axis of rotation is the line from a_4 to a_7. The suffix `r` denotes the mirrored and rotated triangle points.

Use of PSlib.eps in MetaPost

In *Circle Inversions,*MAPS40, 2010, the use of `PSlib.eps` in Metapost has been shown. It complicates, does not obey the SoC principle, and I won't repeat it here.

Annotated References

- Adobe Red, Green and Blue Books. The musts for PostScript programmers.

- Mandelbrot, B(1982); The Fractal structure of Nature. ISBN 07 167 11869.
(This essay of erudition, originality and insight, is about the fundamentals of Math: Euclidean geometry and the dimension concept are widened up into fractal geometry and fractal dimension. A plea is made for fractals to describe natural phenomena: clouds, waves, landscapes, length of coasts with the ill-posed question of length answered by: each coastline has a fractal dimension, The 'montruous' curves of 19^{th} century Math find a honourable niche in fractal geometry, with a fractal dimension added.)

- Minsky, M(1969): Form and Content in Computer Science. Turing Award lecture. In: ACM Turing Award Lectures. The first twenty years 1966-1985. ACM Press. (With TEX and similar quality tools for typesetting, I get the impression that pre-press publications within the TEX-community are out of balance: too much attention is paid to form.)
- Peitgen, H.O, H.Jürgens, D. Saupe(2004 sec.ed.): Chaos and Fractals. New frontiers of Science. (Images of the fourteen chapters of this book cover the central ideas and concepts of chaos and fractals as well as many related topics including: the Mandelbrot set, Julia sets, cellular automata, L-systems, percolation and strange attractors. This new edition has been thoroughly revised throughout. The appendices of the original edition were taken out since more recent publications cover this material in more depth.[26] Instead of the focused computer programs in BASIC, the authors provide 10 interactive JAVA-applets for this second edition via `http://www.cevis.uni-bremen.de/fractals`. An encyclopaedic work. Multiple Reduction Copying Machines, as model for feedback systems, are associated with IFSystems, The Barnsley fern has been elaborated upon and the chaos game is explained. Audience: No mathematical sophistication is required, so a broad audience is aimed at. It portrays the new fields: Chaos and fractals, in an authentic manner. The first edition has been typeset by (La)TEX&Co, the second edition as well, I presume.)
- Peitgen, H.O, P.H. Richter(1986): The Beauty of Fractals. Images of complex dynamical systems. Springer-Verlag. (Frontiers of Chaos. Verhulst Dynamics. Julia Sets and their Computergraphical generation. Sullivan's Classification and Critical Points. The Mandelbrot Set. External Angles and the Hubbard Trees. Newton's method for Complex Polynomials: Cayley's Problem. Newton's method for Real Equations. A discrete Volterra-Lotka System. Magnetism and Complex boundaries. Yang-Lee Zeros. Invited contributions:
Fractals and the Rebirth of Iteration Theory by B. Mandelbrot;
Julia Sets and the Mandelbrot Set by A. Douady;
Freedom, Science, and Aesthetics by G. Eilinger;
Refractions on Science into Art by H.W. Franke.
The book ends with DO IT YOURSELF and DOCUMENTATION.)

- Van der Laan, C.G(1994): Blue's Graphs. MAPS 131, 200–206.
- Van der Laan, C.G(1995): Publishing with TEX. Public Domain. (See TEX archives. `BLUe.tex` comes with `pic.dat` the database of pictures in TEX-alone. No Julia fractals, but some strange attractors have been done by TEX-alone. The advantage of TEX alone approach is portability in place and time. All chapters still compile under pdfTEX without adaptation. The inelegance of the font aspects is inherited from the bitmap-fonts plain TEX-engine. A successor of this work should be based on an OTF-TEX-engine.)

[26] Curious is that the data compression appendix has been taken out while the source still contains blind alleys to the absent appendix; the source has not been adapted, nor are wavelets mentioned, which are used in `.png` and `.jpg` compression. Although the BASIC codes have been taken out, the text is still BASIC biased as can be whitnessed from the attention paid to Turtle Graphics; no recursion which BASIC lacks. The material on the history of the calculation of the digits of π is nice and informative, but a bit out of context.

- Van der Laan, C.G(unpublished, BachoTEX workshop): TEXing Paradigms. (A plea is made for standardized macro writing in TEX to enhance readability and correctness. Topics: Plain's `items` extended, Headache (about headings), Two-part macros. Parametrization I — Options, The wind and hallfwinds (macros for turtle graphics in TEX), It's all in the game — Dialogue with TEX, Loops, Searching, Sorting, Just a little bit of PostScript, FIFO and LIFO sing the BLUes, Syntactic Sugar.)

Conclusions

The use of PostScript pictures in AllTEX documents has a history of 20 years already, to start with the use of `DVIPS`. With pdfTEX the use of direct PostScript inclusion was hampered. `.eps` has to be converted into `.pdf`. Adobe seems to have stopped the support of the run command for library inclusion, which is a big loss. It seems that the use of PostScript pictures is still possible in TEX documents, but the future does not look so good. This holds also for MetaPost and PStricks pictures, because Metapost is just a preprocessor for PostScript and PSTricks uses PostScript under the hood. For the future we need a better and stable graphics tool to cooperate with TEX&Co. On the other hand: is it too optimistic to expect that the PostScript programs will be read and used?
A different class of pictures come from fractals, which are generated in a new way than just drawing.
The Lorenz and Rössler attractor have revolutionized themethod of solution of nonlinear numerical partial differential equations.

Acknowledgements

Thank you Adobe for your maintained, adapted to LanguageLevel 3 since 1997, good old, industrial standard PostScript and `Acrobat Pro` (actually DISTILLER) to view it, Don Knuth for your stable plain TEX, Jonathan Kew for the TEXworks IDE,
Hàn Thế Thành for pdf(La)TEX,
Thank you Jos Winnink and Henk Jansen for proofing. MAPS editors for improving my use of English.
